Bidentate and tridentate coordination of a 2,4-di-*tert*-butyl-substituted bridging amine bis(phenolate) ligand to a palladium(II) center are observed within the same crystal structure, namely dichlorido({6,6'-(ethane-1,2-diylbis(methylazanediyil)]bis(methylene)}bis(2,4-di-*tert*-butylphenol))palladium(II) chlorido(2,4-di-*tert*-butyl-6-{[(2-{[(3,5-di-*tert*-butyl-2-hydroxyphenyl)methyl](methyl)amino]-ethyl}(methyl)amino]methyl}phenolato)palladium(II) methanol 1.685-solvate 0.315-hydrate, $[PdCl_2(C_{34}H_{56}N_2O_2)][PdCl(C_{34}H_{55}N_2O_2)] \cdot 1.685CH_3OH \cdot 0.315H_2O$. Both complexes exhibit a square-planar geometry, with unbound phenol moieties participating in intermolecular hydrogen bonding with co-crystallized water and methanol. The presence of both κ^2 and κ^3 coordination modes arising from the same solution suggest a dynamic process in which phenol donors may coordinate or dissociate from the metal center, and offers insight into catalyst speciation throughout Pd-mediated processes. The unit cell contains dichlorido({6,6'-(ethane-1,2-diylbis(methylazanediyil)]bis(methylene)}bis(2,4-di-*tert*-butylphenol))palladium(II), $\{(L_2)PdCl_2\}$, and chlorido(2,4-di-*tert*-butyl-6-{[(2-{[(3,5-di-*tert*-butyl-2-hydroxyphenyl)methyl](methyl)amino]-ethyl}(methyl)amino]methyl}phenolato)palladium(II), $\{(L_2X)PdCl\}$, molecules as well as fractional water and methanol solvent molecules.

1. Chemical context

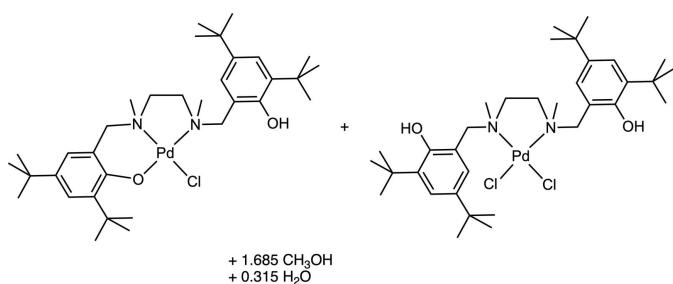

The activity of early transition-metal and rare-earth complexes of amine bis(phenolate) ligands for olefin (Tshuva *et al.*, 2000) and cyclic ester polymerization (Carpentier, 2015) has been well documented. Several studies (Tshuva *et al.*, 2001; Qian *et al.*, 2011) demonstrated that the coordination mode and donor identity play a significant role in the activity of complexes derived from amine bis(phenolate) and related ligands. Amine bis(phenolate) complexes of iron have been employed as catalysts for cross-coupling (Chowdhury *et al.*, 2008), polymerization (Allan *et al.*, 2014) and CO₂ conversion (Andrea *et al.*, 2018) and as functional models for various non-heme metalloenzymes (Karimpour *et al.*, 2013; Strautmann *et al.*, 2011). While a relatively limited number of late transition-metal amine bis(phenolate) complexes have been employed as catalysts, nearly all have been observed to bind through both amine and both phenolate donor atoms to form κ^4 complexes. Related complexes featuring κ^2 or κ^3 coordination modes may offer unique insight into catalyst identity for species that may not be directly observed.

Several related complexes feature ligands similar to these amine bis(phenolate) species bound in a κ^3 fashion. Notably, Zn phenoxy diamine complexes are highly active catalysts for

OPEN ACCESS

the polymerization of lactide. (Williams *et al.*, 2003; Labourdette *et al.*, 2009) Related modification to the amine bis(phenolate) framework generated ‘claw-type’ κ^3 Zn (Song *et al.*, 2012; Wang *et al.*, 2010) and Ti (Zhao *et al.*, 2014) complexes that serve as competent polymerization catalysts. To our knowledge, only one report describes Pd complexes with amine bis(phenolate) ligands bound in a κ^2 or κ^3 coordination mode, in which both amine donors remain bound, and one phenolate donor may bind to the Pd center (Graziano *et al.*, 2019). These species exhibit coordination behavior that varies with the steric parameters of the phenolate *ortho* and *para* substituents, with larger cumyl substituents favoring the formation of κ^2 complexes. In this work, we describe diffraction data for a related Pd complex featuring the ligand {6,6'-(ethane-1,2-diylbis(methylazanediyl)]bis(methylene)}bis(2,4-di-*tert*-butylphenol) bound in both κ^2 or κ^3 coordination modes within a single unit cell. The presence of palladium(II) complexes displaying both κ^2 and κ^3 coordination modes arising from the same solution suggests a dynamic process in which phenol donors may coordinate or de-coordinate based on the electronic demands at the metal center.

2. Structural commentary

The asymmetric unit of the structure (Fig. 1) consists of two distinct palladium(II) complexes of the amine bis(phenolate) {6,6'-(ethane-1,2-diylbis(methylazanediyl)]bis(methylene)}-bis(2,4-di-*tert*-butylphenol) and fractional quantities of methanol and water crystallization solvents. Both metal centers adopt similar distorted square-planar geometric arrangements, in which both nitrogen atoms of the ligand are bound to the Pd center to form a five-membered ring, and either one or two chlorine atoms are present to complete the coordination sphere depending on the coordination mode of the ligand. In both complexes, the N–Pd–N bond angle is similar to those observed for related amine bis(phenolate) Pd complexes (Graziano *et al.*, 2019), as described in Table 1.

Deprotonation and coordination of O1, presumably in the presence of water during crystallization, gives rise to the $[(\kappa^3-N,N,O)\text{PdCl}]$ complex. This complex is only slightly distorted from ideal square-planar geometry (τ_4 parameter = 0.0823; Yang *et al.*, 2007), and Pd1 lies 0.073 Å above the plane defined by O1/N1/N2/C1. The phenol ring containing O2 is disordered by rotation about the C20–C21 bond, such that in the minor component a close O2B–H2C···Cl1 interaction of ~2.065 Å is observed (see Refinement section for details of the

Table 1

disorder). An additional close contact of ~2.460 Å is observed between Cl1 and the O3–H bond of an unbound phenol from the neighboring $[(\kappa^2-N,N)\text{PdCl}_2]$ complex.

The $[(\kappa^2-N,N)\text{PdCl}_2]$ complex also exhibits only minor distortions from an ideal square-planar geometry (τ_4 parameter = 0.0638; Yang *et al.*, 2007), and Pd2 lies within (± 0.001 Å) the plane defined by N3/N4/Cl2/Cl3. Both phenol rings in this complex are disordered by rotation about the C54–C55 bond and the C39–C40 bond, giving rise to a close O3B–H3D···Cl3 interaction of ~2.12 Å and an O4B–H4D···Cl2 interaction of ~2.05 Å, respectively.

Solution NMR data (see *Synthesis and crystallization* section) suggest that the conformations observed in the solid state are retained on the NMR timescale. Signals attributed to both the κ^2 and κ^3 complexes are observed, including signals attributed to the protonated phenol moieties. Signals attributed to the ligand methylene groups are rendered diastereotopic upon coordination of the distal donor atoms to the Pd center, while methylene units for unbound donors remain magnetically equivalent.

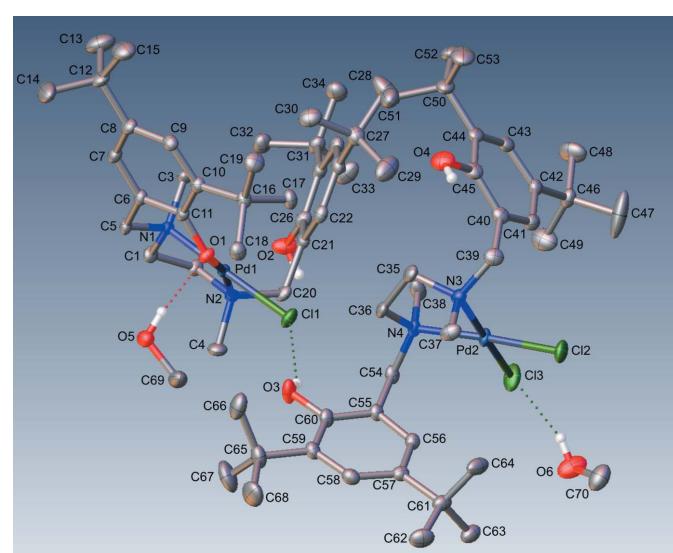

Figure 1

The asymmetric unit of the title compound with only the major components of disorder shown. Displacement ellipsoids are drawn at the 50% probability level. H atoms bonded to C atoms are omitted for clarity and hydrogen bonds are shown as dotted lines.

3. Supramolecular features

Hydrogen bonding (Table 2) is observed between phenol O2—H2, co-crystallized methanol solvent O5—H5, and O1 of a neighboring complex, forming a two-dimensional network in the bc plane between $[(\kappa^3-N,N,O)\text{PdCl}]$ subunits. Details of this interaction are illustrated in Fig. 2, which depicts the interaction between neighboring κ^3 species, viewed along the a axis. Additional O—H \cdots Cl interactions are observed between O3—H3 and Cl1, and O6—H6 and Cl3, though neither of these interactions forms an extended network. The interaction between O3—H3 and Cl1 is of interest as it is the only observed close contact between the κ^2 and κ^3 complexes

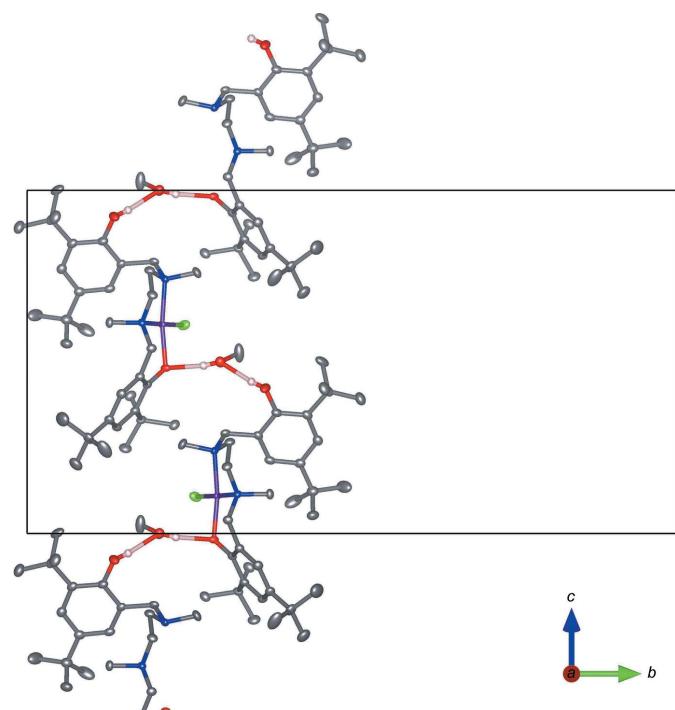

Figure 2

Part of the crystal structure viewed along the a axis, showing hydrogen bonding (in pink) between neighboring κ^3 amine bis(phenolate) Pd^{II} complexes.

within the asymmetric unit. This feature is absent in the minor component, in which the $[(\kappa^2-N,N)\text{PdCl}_2]$ phenol hydroxy moiety O3B—H3D exhibits an intramolecular close contact with Cl3. Within the minor component, a related intramolecular close contact is observed between the remaining $[(\kappa^2-N,N)\text{PdCl}_2]$ phenol hydroxy group O4B—H4D and Cl2.

4. Synthesis and crystallization

Both species within this unit cell are generated upon combining equimolar quantities (0.254 mmol) of the $\{6,6'-(\text{ethane-1,2-diylbis(methylazanediyl)})\text{bis}(\text{methylene})\}\text{bis}(2,4\text{-di-}tert\text{-butylphenol})$ ligand and bis(benzonitrile)dichloropalladium(II) in 5 mL of acetonitrile, using the method reported previously by Wile and co-workers (Graziano *et al.*, 2019) as shown in Fig. 3. The titular compound was obtained as an orange solid (116 mg, 0.169 mmol, 67%). Single crystals suitable for X-ray diffraction studies were grown from a concentrated solution of the metal complex in methanol, layered with distilled water ($\sim 10:1$ v/v).

^1H and ^{13}C NMR spectra reveal signals attributed to both κ^2 and κ^3 Pd complexes in CDCl_3 solution. The equilibrium, and the position of several signals shifts slightly when CD_3OD is employed as the solvent for NMR characterization. The cleanest spectral data were obtained in CDCl_3 , and are reported below. Upon coordination, several methylene H's were rendered diastereotopic. Spectroscopic assignments were confirmed through the use of 2D NMR (COSY, HSQC, HMBC) and polarization transfer (DEPT-135) experiments. ^1H (CDCl_3 , 400.132 MHz) δ = 8.05 (s, 1H, OH), 7.51 (s, 1H, aryl C-H), 7.42 (m, 1H, aryl C-H), 7.36 (m, 2H, aryl C-H), 7.17–7.08 (m, 2H, aryl C-H), 6.83 (s, 1H, OH), 6.55 (m, 1H, aryl C-H), 4.64–4.50 (m, 2H, CH_2), 3.79–3.65 (m, 1H, CH_2), 3.59–3.48 (m, 1H, CH_2), 3.35–3.20 (m, 3H), 3.00 (d, J = 13.6 Hz, 1H, CH_2), 2.92–2.80 (m, 2H, CH_2), 2.73–2.64 (m, 1H, CH_2), 2.47 (s, 1H), 2.37–2.29 (m, 1H, CH_2), 2.19–2.10 (m, 1H, CH_2), 1.62 (s, 3H, CH_3), 1.50 (s, 3H, CH_3), 1.47–1.38 (m, 15H, CH_3), 1.32 (s, 6H, CH_3), 1.30 (s, 3H, CH_3), 1.27 (s, 6H, CH_3), 1.19 (s, 6H, CH_3); $^{13}\text{C}\{^1\text{H}\}$ (CDCl_3 , 100.613 MHz) δ = 158.1 (4°), 153.3 (4°), 141.6 (4°), 139.6 (4°), 136.3 (4°), 129.0 (aryl C-H), 128.7 (4°),

5. Refinement

Crystal data, data collection and structure refinement details are summarized in Table 3.

Water H atoms were restrained to have O–H bond lengths of 0.84 (2) Å, and 1.36 (2) Å H···H distances (DFIX, esd = 0.02 Å). All H atoms attached to carbon atoms as well as phenol and methanol hydroxyl hydrogens were positioned geometrically and constrained to ride on their parent atoms. C–H bond distances were constrained to 0.95 Å for aromatic C–H moieties, and to 0.99 and 0.98 Å for aliphatic CH₂ and CH₃ moieties, respectively. Phenol and methanol O–H distances were constrained to 0.84 Å. Methyl CH₃ and hydroxyl H atoms were allowed to rotate but not to tip to best fit the experimental electron density. *U*_{iso}(H) values were set to a multiple of *U*_{eq}(C/O) with 1.5 for CH₃, OH and water, and 1.2 for C–H, CH₂, units, respectively.

Three of the four phenol hydroxyl groups are positionally disordered by rotation of the aromatic ring. For two of the

three minor moieties, the O–C distance and the 1,3 O to C distances of the minor and major moieties were restrained to be similar (SADI command of *SHELX*, esd = 0.02 Å). Minor O atom O2B was constrained to have the same ADP as the C atom to which it is bonded. Two phenol H-atom positions were positionally restrained based on hydrogen-bonding considerations and to avoid close contacts to C-bound H atoms. Subject to these conditions, the occupancy rates of the major moieties refined to 0.917 (3), 0.857 (4) and 0.899 (4).

A *tert*-butyl group was refined as rotationally disordered. The two moieties were restrained to have similar geometries, the central C atoms to share one ADP, and the *U*^{ij} components of ADPs were restrained to be similar (SIMU command of *SHELX*, esd = 0.01 Å²). Subject to these conditions the occupancy ratio refined to 0.716 (8):0.284 (8).

One solvate methanol molecule was refined as disordered over two orientations, and another to be disordered with a water molecule. The O–C distances of the major and minor methanol molecules were restrained to be similar (SADI, esd = 0.02 Å), and the *U*^{ij} components of ADPs were restrained to be similar for the three methanol and the one water moiety (SIMU, esd = 0.01 Å²). Subject to these conditions the occupancy ratio refined to 0.685 (8):0.315 (8) for the methanol-to-water ratio, and 0.843 (4):0.157 (4) for the methanol-to-methanol ratio.

Crystal data

[PdCl ₂ (C ₃₄ H ₅₆ N ₂ O ₂)]	F(000) = 3022
[PdCl(C ₃₄ H ₅₅ N ₂ O ₂)]·1.685CH ₄ O·0.315H ₂ O	D _x = 1.276 Mg m ⁻³
M _r = 1427.41	Mo K α radiation, λ = 0.71073 Å
Monoclinic, P2 ₁ /c	Cell parameters from 9425 reflections
<i>a</i> = 15.8843 (5) Å	θ = 2.9–36.3°
<i>b</i> = 29.780 (1) Å	μ = 0.64 mm ⁻¹
<i>c</i> = 16.6629 (6) Å	T = 100 K
β = 109.5536 (12)°	Plate, orange
<i>V</i> = 7427.6 (4) Å ³	0.42 × 0.27 × 0.09 mm
Z = 4	

Data collection

Bruker AXS D8 Quest CMOS	87447 measured reflections
diffractometer	22272 independent reflections
Radiation source: sealed tube X-ray source	18396 reflections with $I > 2\sigma(I)$
Triumph curved graphite crystal	$R_{\text{int}} = 0.041$
monochromator	$\theta_{\text{max}} = 30.5^\circ$, $\theta_{\text{min}} = 2.9^\circ$
ω and phi scans	$h = -22 \rightarrow 22$
Absorption correction: multi-scan	$k = -42 \rightarrow 35$
(SADABS; Krause <i>et al.</i> , 2015)	$l = -18 \rightarrow 23$
$T_{\text{min}} = 0.656$, $T_{\text{max}} = 0.747$	

Refinement

Refinement on F^2	22272 reflections
Least-squares matrix: full	900 parameters
$R[F^2 > 2\sigma(F^2)] = 0.033$	186 restraints
$wR(F^2) = 0.076$	Primary atom site location: structure-invariant
$S = 1.03$	direct methods

Secondary atom site location: difference Fourier map

Hydrogen site location: mixed

H atoms treated by a mixture of independent and constrained refinement

$$w = 1/[\sigma^2(F_o^2) + (0.0251P)^2 + 7.3036P]$$

$$\text{where } P = (F_o^2 + 2F_c^2)/3$$

$$(\Delta/\sigma)_{\max} = 0.006$$

$$\Delta\rho_{\max} = 2.12 \text{ e \AA}^{-3}$$

$$\Delta\rho_{\min} = -0.92 \text{ e \AA}^{-3}$$

Special details

Geometry. All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.

Refinement. Three of the four phenol hydroxyl groups are positionally disordered by rotation of the aromatic ring. For two of the three minor moieties the O-C distance and the 1,3 O to C distances of the minor and major moieties were restrained to be similar. Minor O atom O2B was constrained to have the same ADP as the C atom it is bonded to. Two phenol H atom positions were positionally restrained based on H-bonding considerations and to avoid close contacts to C bound H atoms. Subject to these conditions the occupancy rates of the major moieties refined to 0.917 (3), 0.857 (4) and 0.899 (4). A tert butyl group was refined as rotationally disordered. The two moieties were restrained to have similar geometries, the central C atoms to share one ADP, and Uij components of ADPs were restrained to be similar. Subject to these conditions the occupancy ratio refined to 0.716 (8) to 0.284 (8). One solvate methanol molecule was refined as disordered over two orientations, and another to be disordered with a water molecule. The O-C distance of the major and minor methanol molecules were restrained to be similar, and Uij components of ADPs were restrained to be similar for the three methanol and the one water moiety. Water H atoms were restrained to have O-H bond lengths of 0.84 (2) Angstroms, and 1.36 (2) Angstrom H···H distances. Subject to these conditions the occupancy ratio refined to 0.685 (8) to 0.315 (8) for the methanol to water ratio, and 0.843 (4) to 0.157 (4) for the methanol to methanol ratio.
